Bareos 19.2.5 is out

2020-02-04 14:49

The new Bareos version includes a new [oVirt plug-in](#) that supports agentless backups of virtual machines running on oVirt or Red Hat Virtualization (RHV). The plug-in, which was introduced with the first release candidate 19.2.4 rc1, has since been given additional features. It is now possible to store the oVirt credentials in a file instead of using the plug-in options. On top of that, it offers two new options for the restore process: `include_disk_aliases` and `exclude_disk_aliases`. In previous versions it was already possible to exclude disks from the snapshot during the backup.

Since future Bareos versions may support only PostgreSQL, we released a new [tool](#) that migrates the Bareos catalog. `bareos-dbcopy` converts the Bareos database from MySQL to PostgreSQL.

Previously available in the contrib repository, the [Percona XtraBackup plug-in](#) is now an official part of the backup solution and has been moved to the master branch. Users now get the extension automatically when installing Bareos.
